Abstract

We ask whether CEO speech uncertainty during earnings calls predicts firm precautionary cash holdings. Using the speech-uncertainty method of Dzielínski, Wagner, and Zeckhauser (2021), we extend their decomposition from market reactions, analyst behavior, firm performance, and governance outcomes to firm financing-policy outcomes on a panel of U.S. earnings calls from 2002 to 2018. Within-firm increases in the residual Q&A component of CEO speech uncertainty load positively on the cash-to-assets ratio in twelve of twelve specifications under one-tailed tests at the ten-percent level. The cash response amplifies in the cross-section under both financing-friction stress and cash-flow-volatility stress, consistent with a single precautionary channel triggered by two distinct stress conditions. External uncertainty proxies covary with the speech measure in the predicted directions; post-call bid-ask spreads widen and the SEC subsequently issues conference-call comment letters at higher rates following calls with elevated speech uncertainty. Reverse-causality concerns are addressed via cross-sectional modus tollens on the two precautionary triggers; we acknowledge as a limitation that no exogenous-shock identification is pursued.

I Introduction

Earnings calls are a high-frequency setting where CEOs describe firm conditions to outsiders in their own words. We ask whether CEO speech uncertainty during these calls predicts firm precautionary cash holdings. Our measurement is built on the CEO speech-uncertainty method of Dzieliński et al. (2021), which we extend from market reactions, analyst behavior, firm performance, and governance outcomes to firm financing-policy outcomes.

We document that within-firm increases in CEO speech uncertainty during earnings calls predict higher precautionary cash holdings, identifying a real-time signal of firm financing-policy adjustment grounded in the precautionary cash motive (Opler, Pinkowitz, Stulz, & Williamson, 1999; Bates, Kahle, & Stulz, 2009). The relation is positive in twelve of twelve specifications (six contemporaneous and six one-quarter-ahead) under one-tailed tests at the ten-percent level. The cash response amplifies under both financing-friction stress and cash-flow-volatility stress, consistent with a single precautionary channel triggered by two distinct stress conditions (Almeida, Campello, & Weisbach, 2004; Han & Qiu, 2007).

External uncertainty proxies—political risk, economic policy uncertainty, and product-market competition—covary with the speech-uncertainty measure in the predicted directions, supporting the measure's construct validity. Post-call bid-ask spreads widen and SEC conference-call comment letters reference the same speech signal, corroborating the precautionary interpretation through market information-asymmetry and disclosure-insufficiency channels.

Reverse-causality concerns are addressed via cross-sectional modus tollens on the two precautionary triggers, and we acknowledge as a limitation that no exogenous-shock or instrumental-variable identification is pursued.

Our main contribution is to establish CEO speech uncertainty during earnings calls as a real-time signal of firm precautionary cash holdings, extending the method beyond its original scope of market reactions, analyst behavior, firm performance, and governance outcomes. The remainder of the paper proceeds as follows. Section II develops the conceptual framework, hypotheses, and empirical strategy. Section III presents the main empirical analyses—cash holdings, the two precautionary triggers, and the endogeneity treatment. Section IV extends to outsider-reaction tests. Section V concludes with limitations and directions for future work.

II Conceptual Framework and Empirical Strategy

II.1 Conceptual Framework

Firms hold cash to insure against future funding shortfalls. The precautionary cash motive predicts that firms with riskier cash flows or poor access to external capital hold more cash (Opler et al., 1999; Bates et al., 2009). The motive operates through a single mechanism: cash buffers allow firms to fund profitable investment without recourse to costly external capital, mitigating underinvestment when internal cash flow falls short of investment needs. Firms most exposed to this risk—those facing the largest gap between expected internal cash flow and expected required investment—optimally hold the largest buffers.

Two stress conditions amplify the precautionary response. The first is financing-friction stress, in which limited debt-market access leads firms to accumulate cash to safeguard future investment (Almeida et al., 2004); the second is cash-flow-volatility stress, in which volatile operating cash flows lead firms to hold larger buffers to smooth funding gaps (Han & Qiu, 2007). The two stresses are conceptually distinct: one constrains the supply of external capital, the other increases the variance of internal capital. Both trigger the same precautionary response, generating two testable amplifications of the cash response under stress.

II.2 Hypothesis Development

We formalize three hypotheses linking CEO speech uncertainty during earnings calls to firm precautionary cash holdings. The main hypothesis predicts a positive association between speech uncertainty and cash; two amplification hypotheses predict that the association strengthens under each of the two stress triggers identified in Section II.

Speech uncertainty is a candidate real-time signal of the precautionary motive because earnings-call language varies with managerial perceptions of firm conditions (Dzieliński et al., 2021). When CEOs perceive heightened firm-level uncertainty, the precautionary mechanism predicts that firms hold more cash to insure against future funding shortfalls (Opler et al., 1999; Bates et al., 2009).

Hypothesis 1. *An increase in CEO speech uncertainty during an earnings call is associated with a higher cash-to-assets ratio at the firm.*

The two stress conditions of Section II predict heterogeneous amplification of H1. Financing-friction stress operates through the supply of external capital: rated firms can issue debt at low cost, while unrated firms face binding external-finance constraints and accumulate cash to safeguard future investment (Faulkender & Petersen, 2006; Almeida et al., 2004). Cash-flow-volatility stress operates through the variance of internal capital: firms with volatile operating cash flows hold larger buffers to smooth funding gaps (Han & Qiu, 2007). The macro-shock asymmetry of Almeida et al. (2004) provides the theoretical anchor for H1a; the use of within-call CEO speech uncertainty as the within-firm shock signal is a hypothesis-development extension rather than a pre-existing theoretical result.

Hypothesis 1a. *The association between CEO speech uncertainty and cash holdings is stronger for firms facing financing-friction stress (unrated firms) than for firms with debt-market access (rated firms).*

Hypothesis 1b. *The association between CEO speech uncertainty and cash holdings is stronger for firms facing cash-flow-volatility stress (high-volatility firms) than for firms with stable cash flows (low-volatility firms).*

II.3 Estimation of Main Variables

We measure CEO speech uncertainty during earnings calls following Dzielínski et al. (2021). We construct two independent variables of interest from the percentage of uncertainty-words in CEO speech segments: UncResCEO is extracted from the unscripted Q&A segment via the DWZ decomposition, and UncPreCEO is the raw percentage in the scripted presentation segment. We also include ClarityCEO, the persistent CEO-trait component of the same DWZ decomposition, as a control to absorb between-CEO variation in habitual speech style.

UncResCEO is the residual from a regression of Q&A-segment uncertainty on a CEO entity fixed effect and call-level controls (DWZ Eq. 4); it captures within-CEO variation in Q&A uncertainty orthogonal to the CEO's habitual baseline. ClarityCEO is the negative of the CEO entity fixed effect from the same regression (DWZ Eq. 5); it captures the CEO's habitual baseline level of uncertainty-language and enters our specifications as a control absorbing persistent CEO-trait variation. UncPreCEO is the raw percentage of uncertainty-words in the CEO's scripted opening, typically prepared in advance and vetted by investor-relations staff before the call.

Our use of UncPreCEO as an independent variable extends the original method. Dzielínski et al. (2021) use the presentation-segment measure as a control variable in their Q&A residual extraction. We treat UncPreCEO as an independent variable because it may carry an informative signal about firm conditions. We disclose this departure and report results separately for each of the three independent variables in Section III.

II.4 Methodology

We estimate panel regressions of cash holdings on the speech-uncertainty independent variables of interest (UncResCEO and UncPreCEO), the ClarityCEO control, and a vector of firm-level controls. The dependent variable is the cash-to-assets ratio, measured contemporaneously (Cash_t) and at a one-quarter horizon (Cash_{t+1}).

For each dependent-variable horizon, we report a six-cell fixed-effects ladder: (i) industry fixed effects with base controls; (ii) firm fixed effects with base controls; (iii)–(iv) the same two specifications with extended controls; and (v)–(vi) the two extended-control specifications with calendar year-quarter fixed effects added. The base control set follows Bates et al. (2009) (firm size, leverage, market-to-book, ROA, capital expenditure, dividend payer, and operating-cash-flow volatility); the extended set adds sales growth, R&D intensity, cash flow, and stock-return volatility. The lagged dependent variable is included as a base control in all specifications to absorb cash-policy persistence.

Standard errors are clustered at the firm level. Tests of the main hypothesis are one-tailed in the predicted direction; tests of the amplification hypotheses are one-tailed in the predicted direction of the interaction sign.

II.5 Specification and Measurement of Key Constructs

Before turning to the cash analyses, we evaluate the construct validity of the speech-uncertainty measure by testing whether it covaries with established external proxies for firm-relevant uncertainty. If the measure captures uncertainty information rather than mechanical text-frequency artifacts, it should move with proxies that have been validated as uncertainty signals in prior literature.

We use four external proxies: firm-level political-risk exposure measured from earnings-call discussion of political topics (Hassan, Hollander, van Lent, & Tahoun, 2020); aggregate U.S. economic policy uncertainty constructed from newspaper coverage (Baker, Bloom, & Davis, 2016); global economic policy uncertainty as a GDP-weighted average across countries (Davis, 2016); and product-market competition intensity from text-based industry-network similarity (Hoberg & Phillips, 2016).

We expect UncResCEO and UncPreCEO—the within-CEO time-varying components of the speech-uncertainty measure—to load positively on the four proxies. ClarityCEO is a CEO-level fixed effect and is excluded from this test. The construct-validity results are reported alongside the main empirical analyses.

III Main Empirical Analyses

III.A Data, Sample, and Variable Construction

Our sample covers earnings-call observations of U.S. public firms over the period 2002 through 2018 at the firm-quarter frequency. The full call panel comprises 112,968 firm-quarter observations across 2,429 distinct firms. We obtain financial variables from Compustat and earnings-call text features from a vendor-supplied transcript repository.

We exclude firms in financial services and utilities (Fama-French 12 industries 11 and 8). The estimation sample also requires a non-missing lagged dependent variable and is restricted to firms with multiple observations after firm-level fixed-effect singleton dropping. The resulting sample comprises approximately 43,300 firm-quarter observations across 1,376 firms in the contemporaneous specifications and approximately 41,100 firm-quarter observations across 1,321 firms in the lead specifications.

Section II describes the construction of the two CEO speech-uncertainty independent variables of interest (UncResCEO and UncPreCEO) and the ClarityCEO control. The cash-to-assets ratio (Cash_t, Cash_{t+1}) is cash and short-term investments scaled by total assets. Variable definitions are provided in the appendix; summary statistics are reported in Table 1.

III.B Cash Holdings (H1)

Table 2 reports the main estimation results for cash holdings on the speech-uncertainty independent variables of interest. Across the twelve specifications, UncResCEO loads positively on cash holdings in every cell, with one-tailed p-values below the ten-percent level. UncPreCEO is statistically indistinguishable from zero across all twelve specifications.

As a robustness check, Table 3 replicates the main results using a quarterly-expanding-window construction of UncResCEO that eliminates look-ahead bias by re-estimating the speech-uncertainty decomposition each quarter from data available through that quarter only. UncResCEO remains positive and significant in twelve of twelve specifications; the UncPreCEO pattern is preserved.

III.C Constraint Amplification (H1a)

H1a predicts that the cash response amplifies under financing-friction stress, with constrained firms (proxied by an unrated debt status) showing a stronger relation between speech uncertainty and cash holdings than rated firms (Almeida et al., 2004). Table 4 reports estimates of the H1 specification with the addition of an Unrated dummy and its interactions with UncResCEO and UncPreCEO. ClarityCEO is not interacted with Unrated, since the constructed CEO trait does not separate cleanly from cross-sectional firm constraints. The binary rated-vs-unrated partition is adopted from Faulkender and Petersen (2006) verbatim; we do not impose a three-tier investment-grade / below-investment-grade / unrated extension.

The UncResCEO × Unrated interaction loads positively across all eight interaction specifications. The interaction is significant at the ten-percent level under one-tailed tests in the lead-cash specifications with industry fixed effects (columns 5 and 7) but is not significant in the contemporaneous specifications or in the firm-fixed-effects cells. The UncPreCEO × Unrated interaction is direction-consistent in all eight specifications and is significant in one cell (column 3).

The amplification pattern is direction-consistent in every cell. Financing friction amplifies the cash response in the cross-section, with statistical detection in the lead-cash specifications under industry fixed effects. The within-firm variation in the Unrated dummy is sparse—firms rarely transition between rated and unrated status within the sample period—so the interaction coefficient is identified primarily off cross-firm variation in financing friction. Table 5 replicates the analysis using the quarterly-expanding-window construction; the pattern is preserved.

III.D Cash-Flow-Volatility Amplification (H1b)

H1b predicts that the cash response amplifies under cash-flow-volatility stress, with high-volatility firms showing a stronger relation between speech uncertainty and cash holdings than low-volatility firms (Han & Qiu, 2007). Cash-flow volatility (CFvol) is constructed as the coefficient of variation of operating cash flow over a sixteen-quarter rolling window, following Han and Qiu (2007). The HighCFvol indicator equals one when a firm-quarter is at or above the Fama-French 12 industry-year median CFvol. Table 6 reports estimates of the H1 specification with the addition of HighCFvol and its interactions with UncResCEO and UncPreCEO.

The UncPreCEO × HighCFvol interaction loads positively in all eight specifications and is significant at the ten-percent level under one-tailed tests in four of eight cells—all four with industry fixed effects, across both the contemporaneous and lead horizons. The UncResCEO × HighCFvol interaction is direction-consistent in all eight cells and significant in two of eight (lead-cash specifications with industry fixed effects). The interaction effects are absorbed under firm fixed effects, mirroring the pattern in Section III.

Cash-flow-volatility stress amplifies the cash response in the cross-section, with statistical detection across both horizons under industry fixed effects. The H1b specification adopts the cash-flow-volatility construction of Han and Qiu (2007) as a moderator on the speech–cash relation. Together with the financing-friction amplification of Section III, the two interactions cover both stress dimensions of the precautionary cash motive.

We did not pre-register the UncPreCEO×HighCFvol interaction. The base UncPreCEO effect on cash is null in the main panel, and we treat the HighCFvol-tail interaction as a robustness extension rather than a channel-redirecting finding.

III.E Endogeneity

The most consequential endogeneity concern in our setting is reverse causality: cash policy could shape CEO speech rather than the other way around. Within-firm fixed effects and lagged-DV controls absorb time-invariant firm heterogeneity and policy persistence, but neither rules out the reverse arrow at the within-firm time-series level. We address this concern through cross-sectional modus tollens on the two precautionary triggers identified in the conceptual framework: if the forward direction (speech uncertainty → cash) operates through the precautionary mechanism, the cash response should amplify under stress conditions that are themselves cross-sectionally exogenous to within-firm cash-policy choices.

Sections III and III provide such evidence. The cash response amplifies in the cross-section under both financing-friction stress (rated versus unrated debt status) and cash-flow-volatility stress (high versus low CFvol). Neither moderator is plausibly endogenous to within-firm CEO speech: rated/unrated status is determined primarily by firm size and reputation external to quarterly speech variation, and CFvol is constructed from a sixteen-quarter trailing window, predating the contemporaneous speech measure. The observed amplification pattern is consistent with the forward direction and harder to reconcile with a reverse-causation alternative.

Six prior candidate designs were considered and dropped during the project: a CEO sudden-death difference-in-differences, a first-difference reformulation of the Dzielinski-Wagner-Zeckhauser specification, a Lewbel heteroskedasticity-based instrument, weather-shock instruments, the American Jobs Creation Act repatriation experiment, and the Almeida-Campello-Laranjeira-Weisbenner long-term-debt-maturity difference-in-differences. Each failed for design-specific reasons including mechanism mismatch, parallel-trends violations, dual-channel contamination, and absence of a documented cash response to the candidate shock.

Two additional plausibly-exogenous political-risk shocks survived ex-ante design screening and were estimated. We report both designs and their results in Section III; the within-firm modus tollens evidence above remains the load-bearing reverse-causality defense for the present paper.

III.E.4 Auxiliary plausibly-exogenous political-risk shocks (Trump 2016; 2010 Census redistricting)

H1.5 Trump 2016. Following the design template of Hu, Kang, Li, and Lin (2024), we identify firms heavily exposed to both major Trump policy levers—tariffs and the 2017 Tax Cuts and Jobs Act—using the trade-policy and tax-policy sub-topic decompositions of the political-risk measure of Hassan et al. (2020). For each firm we compute the mean of the trade-policy and tax-policy scores over the five-year pre-window 2011Q4–2016Q3 (twenty quarters; prefixed before the November 2016 election). Within each FF12 industry we classify firms as *BothHigh* if both pre-window means lie at or above the industry-own median, *BothLow* if both lie strictly below, and drop the off-diagonal cohorts. Treatment is the difference-in-differences indicator *BothHigh* × *Post*, where *Post* = 1 for calls in 2016Q4 onwards. The sample window is 2014Q3–2018Q4 (the Hu et al. (2024) cutoff window, ending before the 2019 trade-war and Covid shocks). Both cash and CEO speech-uncertainty are estimated as outcomes in parallel four-FE-ladder specifications using the F1D canonical control set; standard errors are firm-clustered. Table 14 reports eight specifications. The difference-in-differences coefficient is small, statistically insignificant, and *negative* in all eight cells—wrong-signed relative to the precautionary prediction. A symmetric single-topic robustness exercise (treatment defined on the trade or tax sub-topic alone) yields sixteen further null cells; the only directionally-correct cell is the firm-year-quarter-FE specification of *HighTax* × *Post* on cash holdings (β = +0.0019, one-tailed p = 0.232), which is statistically insignificant.

H1.6 Redistricting (2010 Census, court-settled 2011). Hasan, Alam, Paramati, and Islam (2022) use the 2010 Census federal congressional redistricting as a plausibly-exogenous shock to firms' political-risk profile. We replicate their Section 5.1 design verbatim and extend it to a parallel speech-uncertainty regression. For each firm we identify the modal headquarters street address over the pre-window 2006–2010 and the post-window 2012–2016, geocode each address via the U.S. Census Geocoder (Public_AR_Current benchmark), and assign the resulting (latitude, longitude) point to a Congressional District by point-in-polygon spatial join against the Lewis, DeVine, Pitcher, and Martis (2013) Congressional District boundary shapefiles—the 111th-Congress map (PRE-redistricting) and the 113th-Congress map (POST-redistricting). Within each pre-redistricting district we rank firms into PRisk tertiles using the firm's five-year-mean overall PRisk (Hassan et al., 2020) measured 2006–2010; we repeat the ranking within each post-redistricting district using the same 2006–2010 PRisk measure but the new district population. Treatment (*Treated*) is +1, 0, or −1 according to whether the firm's tertile increased, stayed unchanged, or decreased. *Post* equals one for calls after 2011 (Hasan et al. (2022) verbatim). The estimation window is 2006–2015 (capped at 2015 to avoid contamination by the 2016 election). To match Hasan et al. (2022)'s Equation 2 verbatim, the H1.6 control set omits the lagged dependent variable that anchors our main-panel specifications; this isolated deviation is required for replication discipline because the AR(1) cash term otherwise absorbs the cumulative cash buildup the redistricting DiD coefficient is designed to identify. Reported adjusted R^2 on cash in the industry-fixed-effects specification (0.287) closely matches Hasan et al. (2022)'s reported value from Table 4 (0.286), confirming the spec is apples-to-apples with the published precedent. An ex-ante mover-rate diagnostic restricted to Hasan et al. (2022)'s 18 redistricted states finds that 47.0% of F1D firms experienced a Congressional-District change between the 111th and 113th maps, compared with the 65.8% rate reported by Hasan et al. (2022); the residual gap likely reflects the F1D earnings-call panel's restriction to the subset of Compustat firms with quarterly call transcripts. Table 15 reports eight specifications. The difference-in-differences coefficient is positive on cash in all four cash specifications (β = +0.0006 to +0.0037, columns 1–4), in the precautionary direction predicted by Hasan et al. (2022), and negative on speech in all four speech specifications (β = −0.0159 to −0.0207, columns 5–8); none of the eight specifications attains statistical significance at conventional levels.

Interpretation. Across thirty-two specifications spanning two independent shocks, four fixed-effect configurations, and two outcomes, none attains statistical significance at conventional levels. The H1.6 redistricting cash coefficients are correctly signed (positive, in the precautionary direction predicted by Hasan et al. (2022)) but small and statistically insignificant; the H1.5 Trump-2016 cash coefficients and all eight speech coefficients are wrong-signed and insignificant. The pattern is informative: at the cross-firm exposure-heterogeneity level, plausibly-exogenous political-risk shocks do not activate measurable joint cash-and-speech co-movement in our panel. Three caveats apply. First, both designs label treatment by absolute (Trump) or relative (redistricting) cross-sectional exposure; they do not exploit within-firm time-series variation, which is precisely the variation our main panel uses to estimate the cash–speech relationship. Second, the F1D earnings-call panel restricts the sample to firms with quarterly call transcripts—a sub-population of the broader Compustat universe over which Hasan et al. (2022) estimates a positive-significant cash response; their reported district-mover rate of 65.8% in the 18 redistricted states exceeds our F1D-restricted 47.0% rate, suggesting the F1D-call panel selects toward larger and more-liquid firms whose redistricting-induced exposure shock is muted relative to the broader cross-section. Third, the residualization step in Dzielínski et al. (2021) absorbs cross-firm clarity heterogeneity, leaving limited variance in UncResCEO for cross-sectionally-defined exposure shocks to move. The within-firm modus tollens evidence in Sections III and III therefore remains the load-bearing reverse-causality defense; the auxiliary shock-based evidence in this subsection neither corroborates nor refutes that defense, but does constrain interpretation: the cash–speech link we document is most cleanly identified within firm over time, not across firms by exposure level.

IV Additional Analyses

IV.A Market Information-Asymmetry Channel: Post-Call Bid-Ask Spread

The market information-asymmetry channel predicts that post-call bid-ask spreads widen following CEO speeches with higher uncertainty, as outside investors price-protect against the informed-trading risk that the speech signal makes salient. We measure the post-call response on a twenty-five-trading-day window beginning the call day. Table 12 reports estimates of the speech-uncertainty independent variables on the twenty-five-day spread level, in basis points, under the four-step fixed-effects ladder and the market-microstructure controls (stock price, share turnover, daily return volatility, absolute earnings surprise) that the spread literature requires.

UncPreCEO loads positively on the contemporaneous-quarter spread in all six contemporaneous specifications and is significant at the ten-percent level under one-tailed tests in four of six cells. The pattern preserves under firm fixed effects across all three control specifications; under industry fixed effects, significance is preserved with base controls but is absorbed once the market-microstructure controls are added (columns 3 and 5). The lead-quarter specifications are null. UncResCEO loads null across both horizons.

The contemporaneous market response is consistent with the precautionary interpretation of the speech signal: outside investors impound the signal into liquidity provision in the same quarter, widening spreads alongside the within-firm cash response documented in Section III. The presentation-segment component of CEO speech, rather than the residual Q&A component, carries the market-relevant signal at this horizon.

IV.B Disclosure-Insufficiency Channel: Conference-Call Comment Letter (CCCL)

The disclosure-insufficiency channel predicts that the SEC issues a Conference-Call Comment Letter (CCCL) when an earnings call surfaces disclosure problems that warrant follow-up review. Following Lerman, Steffen, and Zhang (2026), who introduce and validate the CCCL as a regulatory-scrutiny indicator referencing the earnings call, we measure CCCL receipt as a binary outcome and estimate a linear probability model. Table 13 reports estimates of the speech-uncertainty independent variables on CCCL receipt under the four-step fixed-effects ladder.

UncPreCEO loads positively on CCCL receipt in all six specifications and is significant at the ten-percent level under one-tailed tests in four of six cells. Significance is preserved in three of the four specifications with extended controls (columns 3, 4, and 6) and is absorbed only under industry-year-quarter fixed effects with extended controls (column 5). UncResCEO loads null across all six specifications.

The pattern is consistent with the disclosure-insufficiency interpretation: presentation-segment uncertainty during the earnings call associates with a higher probability that the SEC subsequently issues a comment letter referring to the call. As in Section IV, the presentation-segment component of CEO speech, rather than the residual Q&A component, carries the regulator-relevant signal.

V Conclusion

V.1 Summary

This paper documents that within-firm increases in CEO speech uncertainty during earnings calls predict higher precautionary cash holdings. The residual

Q&A component of CEO speech-uncertainty (UncResCEO) loads positively on the cash-to-assets ratio in twelve of twelve specifications under one-tailed tests at the ten-percent level. The cash response amplifies under both financing-friction stress and cash-flow-volatility stress, consistent with a single precautionary channel triggered by two distinct stress conditions (Almeida et al., 2004; Han & Qiu, 2007).

The contribution is to establish CEO speech uncertainty as a real-time signal of firm precautionary cash holdings, extending the speech-uncertainty method of Dzielínski et al. (2021) beyond its original scope—market reactions, analyst behavior, firm performance, and governance outcomes—to firm financing-policy outcomes. Outsider reaction corroborates the precautionary interpretation through two channels: post-call bid-ask spreads widen contemporaneously, and the SEC subsequently issues Conference-Call Comment Letters at higher rates following calls with elevated speech uncertainty.

The within-firm cash response loads on the residual Q&A component (UncResCEO), while the outsider-reaction signal loads on the presentation-segment component (UncPreCEO); the asymmetry sits within the speech-uncertainty decomposition of Dzielínski et al. (2021) rather than being imposed. The within-firm cash response and the outsider-reaction responses operate through theoretically distinct mechanisms; we do not claim a causal bridge between them.

Reverse-causality concerns are addressed through cross-sectional modus tollens on the two precautionary triggers identified in the conceptual framework. We additionally estimate two auxiliary plausibly-exogenous political-risk-shock designs—a 2016-presidential-election difference-in-differences on firms heavily exposed to both major Trump policy levers (tariffs and the Tax Cuts and Jobs Act) and a verbatim replication of the 2010-Census redistricting design of Hasan et al. (2022) that uses geocoded firm headquarters paired with the Lewis et al. (2013) Congressional District boundary shapefiles. The redistricting design produces correctly-signed but statistically-insignificant cash coefficients in the precautionary direction predicted by Hasan et al. (2022); all other cells (the four redistricting speech specifications and the eight Trump-2016 specifications across cash and speech) are wrong-signed and statistically insignificant. None of the thirty-two cells attains conventional significance. We discuss the interpretation of these auxiliary results in Section V.

V.2 Limitations

The primary limitation of our identification strategy is the absence of a load-bearing exogenous-shock or instrumental-variable defense of the speech-uncertainty → cash direction. As discussed in Section III, we identify the forward direction through cross-sectional modus tollens on two precautionary triggers; six candidate exogenous-shock and instrumental-variable designs were considered and dropped during the project. The CEO sudden-death difference-in-differences was dropped for mechanism mismatch: the shock affects multiple firm channels simultaneously rather than a narrow speech channel. The first-difference reformulation of the Dzielínski et al. (2021) specification was dropped because it addresses a time-invariant firm-trait threat that within-firm fixed effects in our main panel already absorb. The Lewbel heteroskedasticity-based instrument failed the Wu-Hausman test for OLS-inconsistency. Weather-shock instruments lack a documented cash-holdings response to identify a first stage. The 2004 American Jobs Creation Act repatriation experiment was dropped because the load-bearing public-finance evidence on this shock reports no cash-holdings response post-shock. The long-term-debt-maturity difference-in-differences anchored on the 2007 credit-crisis maturing-debt cohort was dropped for dual-channel contamination: the shock pushes cash in the opposite direction of the hypothesized speech channel via a separate forced-deployment mechanism.

Two further plausibly-exogenous political-risk-shock designs survived ex-ante screening and were estimated; we report both in Section III. The first follows Hu et al. (2024), exploiting the November 2016 U.S. presidential election as a shock to firms heavily exposed on both Trump policy levers (trade and tax). The second replicates the 2010-Census redistricting design of Hasan et al. (2022) verbatim, with headquarters-to-Congressional-District assignment performed via Census Geocoder lat/lon plus point-in-polygon spatial join against the Lewis et al. (2013) Congressional District boundary shapefiles, and extends the design to a parallel speech-uncertainty outcome. None of the thirty-two specifications (eight per design per outcome) attains statistical significance at conventional levels. The four H1.6 cash specifications produce correctly-signed coefficients (β = +0.0006 to +0.0037) in the precautionary direction predicted by Hasan et al. (2022); the four H1.6 speech specifications and all eight H1.5 Trump-

2016 specifications yield wrong-signed insignificant coefficients. Three interpretive caveats apply. First, both designs label treatment by cross-sectional exposure rather than within-firm time-series variation; the latter is precisely the variation our main panel uses to estimate the cash–speech relationship. Second, the F1D earnings-call panel restricts the sample to firms with quarterly call transcripts: Hasan et al. (2022)'s reported 65.8% district-mover rate in the 18 redistricted states exceeds our F1D-restricted 47.0% rate, suggesting the call-firm sample selects toward larger and more-liquid firms whose redistricting-induced exposure shock is attenuated relative to the broader Compustat cross-section over which their positive-significant cash result is estimated. Third, the residualization step in Dzielínski et al. (2021) absorbs cross-firm clarity heterogeneity, leaving limited variance in UncResCEO for cross-sectionally-defined exposure shocks to move. The auxiliary null results therefore neither corroborate nor refute the within-firm modus tollens evidence in Sections III and III; they constrain interpretation by indicating that the cash–speech link we document is most cleanly identified within firm over time, not across firms by exposure level.

Any future exogenous-shock identification compatible with our forward-direction hypothesis must satisfy a strict requirement set: exogeneity to firm cash policy, a narrow speech channel without parallel direct-on-cash mechanisms, direction-compatibility on any non-speech channels, a first stage on speech, cross-sectional intensity variation, parallel trends on both cash and speech, a top-tier journal anchor, and an adequate treated-firm count. The strongest a-priori candidate we are aware of is discussed in Section V.

Two methodological-extension disclosures bear noting. We use UncPreCEO as an independent variable, whereas Dzielínski et al. (2021) treat the presentation-segment measure as a control in their residual-extraction step. We extend the speech-uncertainty method to firm financing-policy outcomes; Dzielínski et al. (2021) themselves report null effects of UncResCEO and UncPreCEO on the market-reaction outcomes that motivated the original method, and our positive cash-side findings should be read in light of that scope difference.

The dependent variable follows the linear cash-to-assets specification of Bates et al. (2009); an OPSW log-of-cash-to-net-assets robustness specification is flagged as a planned extension but is not estimated in the present draft.

V.3 Future Work

Two natural follow-up directions emerge from the auxiliary shock-based estimates reported in Section III. First, both designs we estimated label treatment by cross-sectional exposure (firm-level pre-shock PRisk percentile or rank-tertile within congressional district); the within-firm time-series variation that anchors our main panel estimates is not exploited. A within-firm time-series shock—one whose timing varies idiosyncratically by firm rather than by industry-median exposure—would test the same forward direction with different identifying variation. Candidate designs include firm-level customer concentration shocks, executive-team turnover events with documented narrow speech channels, and product-market disruption events; each requires a documented first stage on speech and direction-compatibility analysis on parallel non-speech channels.

Second, the residualization step of Dzielínski et al. (2021) absorbs cross-firm clarity heterogeneity by construction. A complementary outcome variable that retains more cross-sectional cross-firm variation—for example the raw presentation-segment uncertainty UncPreCEO before residualization, or the unresidualized Q&A-segment uncertainty UncAnsCEO—may be more responsive to cross-sectionally-defined exposure shocks. We flag both directions as potential extensions but do not pursue them in the present paper.

Notes: Summary statistics for variables used in the hypothesis tests. Sample period: 2002–2018. Anchor sample (H1, Main): 88,205 earnings-call observations across 1,884 firms. Unit column: C = call-level, F = firm-year. N varies by row because each variable is summarized on its anchor panel's Main sample (complete cases per variable); per-suite samples differ due to lags, control availability, and merges.

Notes: $^{*}p < 0.10$, $^{**}p < 0.05$, $^{***}p < 0.01$ (one-tailed for IVs, $\beta > 0$; two-tailed for controls). Significant coefficients in **bold**. Standard errors (in parentheses) clustered at firm level. Main sample (excludes financial and utility firms). 2006-2015 (5-year pre-window per Hasan 2022 plus post-2011 redistricting effective period; cut at 2015 to avoid Trump 2016 contamination). Treated$_{redist}$ assigned per Hasan 2022 Section 5.1 verbatim methodology: firm-rank tertile within congressional district before vs after 2011 redistricting. HQ-to-CD via Census Geocoder (Public_AR_Current benchmark) firm HQ lat/lon point-in-polygon spatial join against Lewis et al. 2013 Congressional District boundary shapefiles (PRE = 111th-Congress; POST = 113th-Congress). Post = 1 if year ¿ 2011 (Hasan verbatim). R^2 includes absorbed fixed effects (not within-R^2).

A Variable Definitions

This appendix lists every variable used in the empirical analyses, with construction formula, data source, and originating reference. Variable names follow paper-standard conventions where available (Dzieliński et al. 2021 for speech measures, Bates et al. 2009 for cash-holdings controls); deviations from source-paper frequency or sample are documented in the formula column.

A.1 Sample Manifest

Name	Description / Formula	Source	Reference
`file_name, ceo_id, ceo_name, gvkey, ff12_code, ff12_name, start_date`	Master sample manifest with CEO, firm, and industry identifiers	outputs/1.4_AssembleManifest	

A.2 Text/Linguistic Variables

Name	Description / Formula	Source	Reference
`ClarityCEO`	CEO clarity persistent-style component (DWZ Eqn 5). *Formula:* $\text{ClarityCEO}_i = -\widehat{\text{FE}}_i$ where $\widehat{\text{FE}}_i$ is the CEO-i fixed-effect estimate from the panel regression $\text{UncAnsCEO}_{ic} = \alpha + \sum_i \text{FE}_i \cdot \mathbb{1}[\text{CEO} = i] + \mathbf{X}_{ic}\gamma + \varepsilon_{ic}$ over the call-level Q&A uncertainty panel; controls $\mathbf{X}$ are the DWZ extended-controls vector. The sign flip on $\widehat{\text{FE}}_i$ makes higher ClarityCEO mean "CEO speaks more clearly" (lower mean uncertainty). Persistent CEO trait.	.../ceo_clarity_extended/	Dzielínski et al. (2021) (Section 4.4 Eqn 5, p.16)
`ClarityCEO_QtrExp`	ClarityCEO under within-tenure expanding window. *Formula:* As ClarityCEO, but the CEO fixed-effect regression is re-estimated on an expanding within-CEO window using only calls of CEO i available up to and including focal call c. Strictly look-ahead-free.	.../ceo_clarity_expanding/	thesis QtrExp variant of Dzielínski et al. (2021) Eqn 5
`NegCall`	Entire-call negative sentiment percentage. *Formula:* Ratio of negative words to total words in the entire call, based on LM 2011 negative-words list. Per DWZ 2021 Appendix Table A.1: 'percentage of negative words in all words spoken by the CEO, CFO and analysts attending the call.'	outputs/2_Textual_Analysis/2.2_Variables	Dzielínski et al. (2021) (Section 4.4, p.18; Appendix Table A.1, p.54)
`UncAnsCEO`	CEO-only Q&A uncertainty percentage. *Formula:* CEO Q&A uncertainty (%) = UnctWordsAnsCEO / WordsAnsCEO (DWZ 2021 Eqn 2). Uncertainty wordlist = LM 2011 Master Dictionary 'uncertainty' list (297 words, Aug 2014 version). CEO identified via Execucomp ceoann field.	outputs/2_Textual_Analysis/2.2_Variables	Dzielínski et al. (2021) (Section 4.2, Eqn 2, p.13; Appendix Table A.1, p.54)
`UncPreCEO`	CEO-only presentation uncertainty percentage. *Formula:* CEO Presentation uncertainty (%) = UnctWordsPreCEO / WordsPreCEO (DWZ 2021 Eqn 1). Uncertainty wordlist = LM 2011 (297 words).	outputs/2_Textual_Analysis/2.2_Variables	Dzielínski et al. (2021) (Section 4.2, Eqn 1, p.13; Appendix Table A.1, p.54)
`UncQue`	Analyst Q&A uncertainty percentage. *Formula:* Analyst Q&A uncertainty (%) = UnctWordsQue / WordsQue (DWZ 2021 Eqn 3). Uncertainty wordlist = LM 2011 (297 words).	outputs/2_Textual_Analysis/2.2_Variables	Dzielínski et al. (2021) (Section 4.2, Eqn 3, p.13; Appendix Table A.1, p.54)
`UncResCEO`	CEO Q\&A residual call-state uncertainty component (DWZ Eqn 4). *Formula:* $\widehat{\varepsilon}_{ic}$ = the residual from the panel regression $\text{UncAnsCEO}_{ic} = \alpha + \sum_i \text{FE}_i \cdot \mathbb{1}[\text{CEO} = i] + \mathbf{X}_{ic}\gamma + \varepsilon_{ic}$ that produces ClarityCEO. By OLS first-order conditions, the within-CEO mean of UncResCEO is exactly zero by construction. Captures call-level deviation in CEO Q&A uncertainty after stripping out the persistent CEO mean.	.../ceo_clarity_extended/	Dzielínski et al. (2021) (Section 4.4 Eqn 4, p.16)

(continued on next page)

(continued from previous page)

Name	Description / Formula	Source	Reference
`UncResCEO_QtrExp`	UncResCEO under within-tenure expanding window. *Formula:* As UncResCEO, but the residualization regression is re-estimated on an expanding within-CEO window. Strictly look-ahead-free.	.../ceo_clarity_expanding/	thesis QtrExp variant of Dzieliński et al. (2021) Eqn 4

A.3 Financial / Market Variables

Name	Description / Formula	Source	Reference
`BGTLevel_Spread`	Compute BGT (2018) long-window closing bid-ask spread around earnings calls. *Formula:* CRSP via get_raw_daily_data (closing BID/ASK) (see module: src/f1d/shared/variables/bgt_long_window_spread.py)	CRSPviaget_raw_daily_data	Bushee, Gow & Taylor (2018, JAR) [window]; Lee (2016, TAR) [formula]
`Capex`	Build Capex = capxy_annual / atq_lag from raw Compustat quarterly data. *Formula:* Compustat/capxy_Q4/atq (see module: src/f1d/shared/variables/capex_intensity.py)	Compustat/capxy_Q4/atq	Bates, Kahle & Stulz (2009, JF)
`CashFlowAt`	Build CashFlow = oancfy / atq from raw Compustat quarterly data. *Formula:* Compustat/oancfy/atq (see module: src/f1d/shared/variables/cash_flow.py)	Compustat/oancfy/atq	Bates, Kahle & Stulz (2009, JF)
`CashRatio`	Build CashRatio = cheq / atq from raw Compustat quarterly data. *Formula:* Compustat/cheq/atq (see module: src/f1d/shared/variables/cash_holdings.py)	Compustat/cheq/atq	Bates et al. (2009) (Section II, p.1991; BKS use annual che/at — we use quarterly cheq/atq for panel alignment)
`DailyVola`	Annualized stock-return volatility computed on the inter-call CRSP daily-return window. *Formula:* Annualized standard deviation of CRSP daily returns over the inter-call window [prev_call_date + 5 days, call start_date - 5 days], requiring ¿= 10 trading days. Formula: std(daily_ret) * sqrt(252) * 100, expressed in percent.	CRSP/RET	Dzieliński et al. (2021)
`DivDummy`	Build DivDummy = (dvy ¿ 0).astype(float) from raw Compustat quarterly data. *Formula:* Compustat/dvy¿0 (see module: src/f1d/shared/variables/dividend_payer.py)	Compustat/dvy¿0	Bates et al. (2009) (Section IV, p.2000; dividend payout dummy based on common dividends)
`EarnVol`	Builder for Earnings Volatility (earnings_volatility) variable. *Formula:* Compustat (see module: src/f1d/shared/variables/earnings_volatility.py)	Compustat	Duong, Do, and Do (2025) (Appendix B, p.30; 3-year rolling std of qoq asset-scaled earnings)
`FirmMat`	Builder for Firm Maturity (firm_maturity) variable. *Formula:* Compustat (see module: src/f1d/shared/variables/firm_maturity.py)	Compustat	Biddle, Hilary, and Verdi (2009) (Appendix A, p.130; years since first CRSP appearance); alt Leary and Roberts (2010) (App.˜A p.354)
`Leverage`	Build Leverage = (dlcq + dlttq) / atq (interest-bearing debt only). *Formula:* Compustat/dlcq,dlttq,atq (see module: src/f1d/shared/variables/book_lev.py)	Compustat/dlcq,dlttq,atq	Bates et al. (2009), rz1995
`lnAssets`	Build Size = ln(atq) from raw Compustat quarterly data. *Formula:* Compustat/atq (see module: src/f1d/shared/variables/size.py)	Compustat/atq	Dzieliński et al. (2021)
`PRisk`	Match quarterly PRisk onto each earnings call by (gvkey, calendar_quarter). *Formula:* Hassan et al. (2019) quarterly PRisk (see module: src/f1d/shared/variables/prisk_q.py)	Hassanetal.	Hassan et al. (2020)

(continued on next page)

(continued from previous page)

Name	Description / Formula	Source	Reference
RDSales	Build RDSales = xrdy_Q4-annual / saley_Q4-annual from Compustat quarterly data, following Bates 2009 / Jiang-John-Larsen 2021 R&D-over-sales convention. *Formula:* Compustat/xrdy,saley (Q4-annual YTD; missing xrd treated as zero; non-positive sales treated as NaN; see module: src/f1d/shared/variables/_compustat_engine.py L984-993)	Compustat/xrdy,saley	Bates et al. (2009), jjl2021
ROA	Build ROA = iby_annual / avg_assets from Compustat quarterly data. *Formula:* Compustat/iby,atq (see module: src/f1d/shared/variables/roa.py)	Compustat/iby,atq	Wang (2020), Dzielínski et al. (2021)
SalesGrowth	Build SalesGrowth from raw Compustat quarterly data (annual Q4 panel). *Formula:* Compustat/saley_Q4_YoY (see module: src/f1d/shared/variables/sales_growth.py)	Compustat/saley_Q4_YoY	Biddle et al. (2009) (Section 3.2, p.117; pct change in sales)
sCFO	Build sCFO = rolling 5-year std (min 3 yrs) of (oancfy/atq_{t-1}) per gvkey. *Formula:* Compustat/oancfy/atq_{t-1} rolling std (see module: src/f1d/shared/variables/ocf_volatility.py)	Compustat/oancfy/atq_{t-1}rollingstd	Biddle et al. (2009) (Appendix A, p.130; 5-year rolling std of CFO/avg assets)
StockPrice	Compute stock price at earnings call date (VECTORIZED). *Formula:* CRSP via get_raw_daily_data (see module: src/f1d/shared/variables/stock_price.py)	CRSPviaget_raw_daily_data	Amiram, Owens, and Rozenbaum (2016) (Appendix A, p.137; daily CRSP stock price; justification cites Stoll 1978)
SurpDec	Signed-quintile earnings surprise rank (-5 to +5) within calendar quarter. *Formula:* Signed quintile rank of percentage earnings surprise per DWZ 2021 Appendix Table A.1: raw surprise = (actual - consensus forecast earnings) / share price 5 trading days before announcement, x 100. Firms grouped into 5 bins of positive surprise (+5 largest through +1 smallest positive), 0 for zero surprises, and 5 bins of negative surprise (-1 smallest negative through -5 largest negative). DWZ footnote 32 notes this decile convention follows Hirshleifer, Lim & Teoh (2009) and DellaVigna & Pollet (2009).	.../variables/earnings_surprise.py	Dzielínski et al. (2021) (Appendix Table A.1, p.55; convention cites DellaVigna-Pollet 2009 + Hirshleifer-Lim-Teoh 2009)
TobinsQ	Build TobinsQ = (AT + cshoq*prccq - CEQ) / AT from raw Compustat quarterly data. *Formula:* Compustat/(atq+cshoq*prccq-ceqq)/atq (see module: src/f1d/shared/variables/tobins_q.py)	Compustat/	Bates, Kahle & Stulz (2009, JF)
Turnover	Compute share turnover at earnings call date (VECTORIZED). *Formula:* CRSP via get_raw_daily_data (see module: src/f1d/shared/variables/turnover.py)	CRSPviaget_raw_daily_data	Amihud (2002) (Section 2.1, p.33; alt rolling-window def in Chang, Dasgupta, and Hilary (2006) Appendix B p.3045)

A.4 Econometric / Indicator Variables

Name	Description / Formula	Source	Reference
HighCFvol	High cash-flow-volatility moderator (H1.3). *Formula:* Binary = 1 if firm-quarter Han-Qiu (2007) cash-flow-volatility (16-quarter rolling std of quarterly OCF / |mean| of quarterly OCF, lagged one quarter per Han-Qiu Eqn 5 RHS) is at or above the within-Fama-French-12-industry-year median; 0 otherwise.	runtime	Han and Qiu (2007); thesis (H1.3 split convention)
Lagged_DV	Generic lagged-DV control (1Q lag of suite-specific DV). *Formula:* 1-quarter lag of the dependent variable, constructed at runtime per spec (DV varies per suite). Always included as base control to absorb persistence.	runtime	thesis convention (per feedback_lagged_dv.md)

(continued on next page)

(continued from previous page)

Name	Description / Formula	Source	Reference
Unrated	No-rating subsample indicator (H1.2). *Formula:* Binary = 1 if firm has no S&P rating at call date; 0 otherwise.	runtime	thesis (H1.2 rating subsample)
z_log_TotalSimilarity	z-scored log of HP 2016 product-market-similarity (IV in H23 competition test). *Formula:* z-score of log(1 + TotalSimilarity) computed within year. TotalSimilarity = HP 2016 firm-year product market similarity score (sum of pairwise cosine similarities × 100).	runtime	Hoberg and Phillips (2016)

A.5 Runtime Derivatives (Lead/Lag/Centered/Interaction)

Name	Description / Formula	Source	Reference
AbsSurpDec	Absolute earnings surprise quintile magnitude. *Formula:* abs(SurpDec) — unsigned magnitude of signed-quintile earnings surprise rank, values 0-5.	runtime	thesis (magnitude control independent of sign)
BGTLevel_Spread_lead1	1Q lead of BGTLevel_Spread. *Formula:* 1-quarter lead of BGTLevel_Spread	runtime	Bushee, Gow, and Taylor (2018), lee2016
CashRatio_lead	1Q lead of CashRatio. *Formula:* 1-quarter lead of CashRatio	runtime	see base var
ClarityCEO_c	Mean-centered ClarityCEO. *Formula:* ClarityCEO minus its sample mean (mean-centered for interaction interpretability).	runtime	thesis (interaction interpretability)
ClarityCEO_QtrExp_c	Mean-centered ClarityCEO_QtrExp. *Formula:* ClarityCEO_QtrExp minus its sample mean.	runtime	thesis (interaction interpretability)
PRisk_lag2	2Q lag of PRisk. *Formula:* 2-quarter lag of PRisk	runtime	Hassan et al. (2020)
UncPreCEO_c	Mean-centered UncPreCEO. *Formula:* UncPreCEO minus its sample mean (mean-centered for interaction interpretability).	runtime	thesis (interaction interpretability)
UncPreCEO_c_x_HighCFvol	Interaction: UncPreCEO_c $\times$ HighCFvol (H1.3). *Formula:* Product: UncPreCEO_c * HighCFvol.	runtime	thesis (CFvol moderator interaction)
UncPreCEO_c_x_Unrated	Interaction: UncPreCEO_c $\times$ Unrated (HFC). *Formula:* Product: UncPreCEO_c * Unrated.	runtime	thesis (HFC interaction)
UncResCEO_c	Mean-centered UncResCEO. *Formula:* UncResCEO minus its sample mean (mean-centered for interaction interpretability).	runtime	thesis (interaction interpretability)
UncResCEO_c_x_HighCFvol	Interaction: UncResCEO_c $\times$ HighCFvol (H1.3). *Formula:* Product: UncResCEO_c * HighCFvol.	runtime	thesis (CFvol moderator interaction)
UncResCEO_c_x_Unrated	Interaction: UncResCEO_c $\times$ Unrated (HFC). *Formula:* Product: UncResCEO_c * Unrated.	runtime	thesis (HFC interaction)

(continued on next page)

(continued from previous page)

Name	Description / Formula	Source	Reference
`UncResCEO_QtrExp_c`	Mean-centered UncResCEO_QtrExp. *Formula:* UncResCEO_QtrExp minus its sample mean.	runtime	thesis (interaction interpretability)
`UncResCEO_QtrExp_c_x_Unrated`	Interaction: UncResCEO_QtrExp_c $\times$ Unrated (HFC QtrExp). *Formula:* Product: UncResCEO_QtrExp_c * Unrated.	runtime	thesis (HFC QtrExp interaction)

A.6 Macro / Regulatory Variables

Name	Description / Formula	Source	Reference
`CCCL`	SEC comment letter received (binary, forward-looking) *Formula:* 1 if SEC comment letter received in next quarter, 0 otherwise	inputs/EDGAR_CommentLetters	cdm2013
`GEPU_log`	Davis (2016, NBER WP 22740) Global Economic Policy Uncertainty (GEPU) index (log-transformed, current-$ GDP weights) *Formula:* log(GEPU_current) — GDP-weighted average of 16 country EPU indices, matched by calendar month of call start_date	inputs/EconomicPolicyUncertaintyIndex/Global	Davis (2016)
`US_EPU_log`	Baker, Bloom & Davis (2016, QJE) US News-Based Economic Policy Uncertainty index (log-transformed) *Formula:* log(News_Based_Policy_Uncert_Index) matched by calendar month of call start_date	inputs/EconomicPolicyUncertaintyIndex/US	Baker et al. (2016)
